Reinforcement Learning

Basic Types of Machine Learning Algorithms

Supervised Learning

Unsupervised Learning

Reinforcement Learning

- Labeled data
- Direct and quantitative evaluation
- Learn model from „ground truth“ examples
- Predict unseen examples

Supervised Learning

Basic Notation:

Data is given as tuples

$$(X, Y) := \{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$$

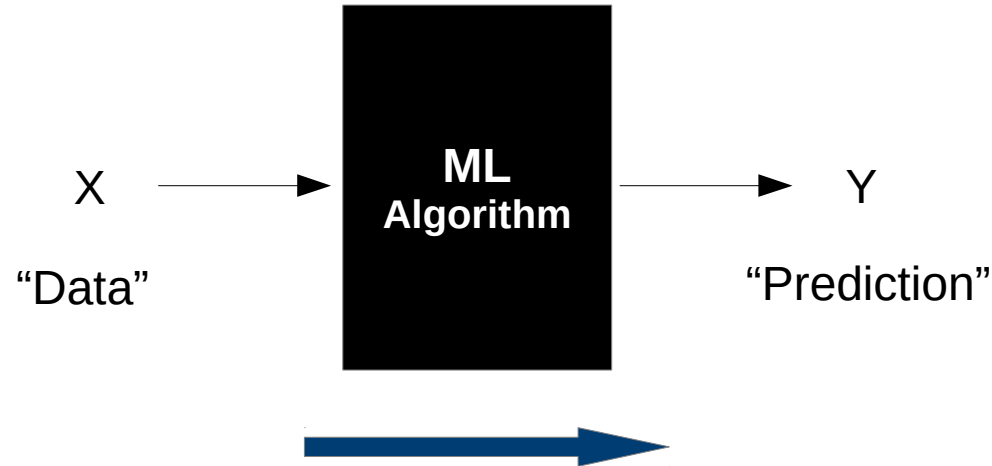

Where X is the actual **data** (sample) and y the associated **label**.

For most ML algorithms (**many Deep Learning algorithms are an exception**)

$$x_i \in \mathbb{R}^n, y_i \in \mathbb{R}$$

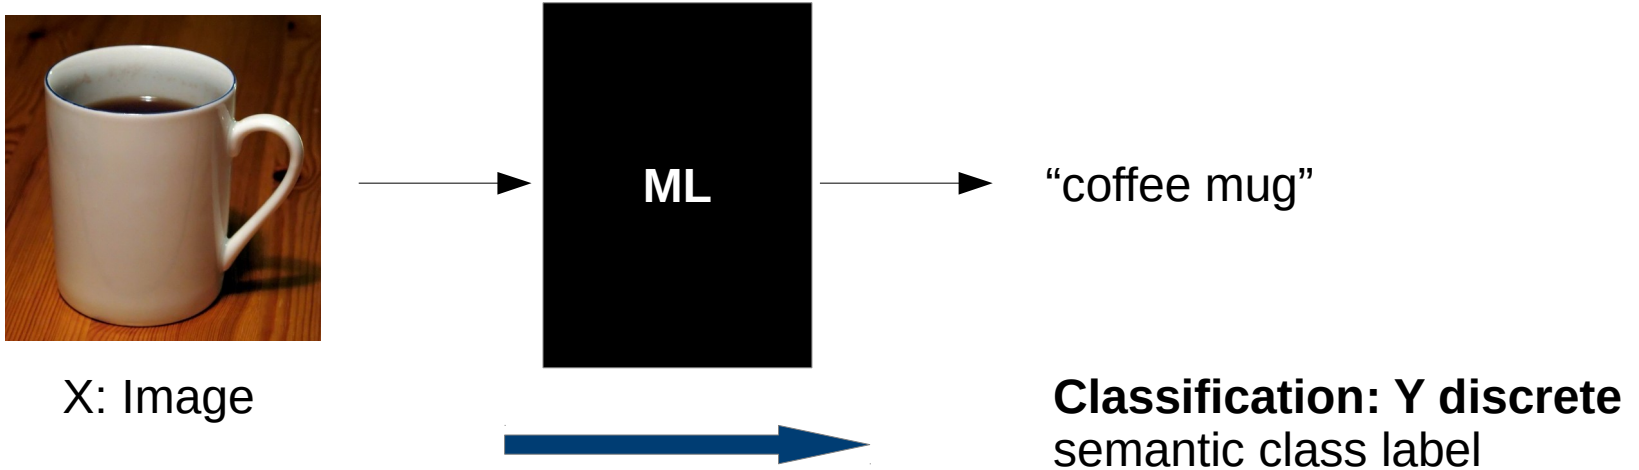

The data has to be represented as vectors and the labels are scalars.

Supervised Learning as a Black Box

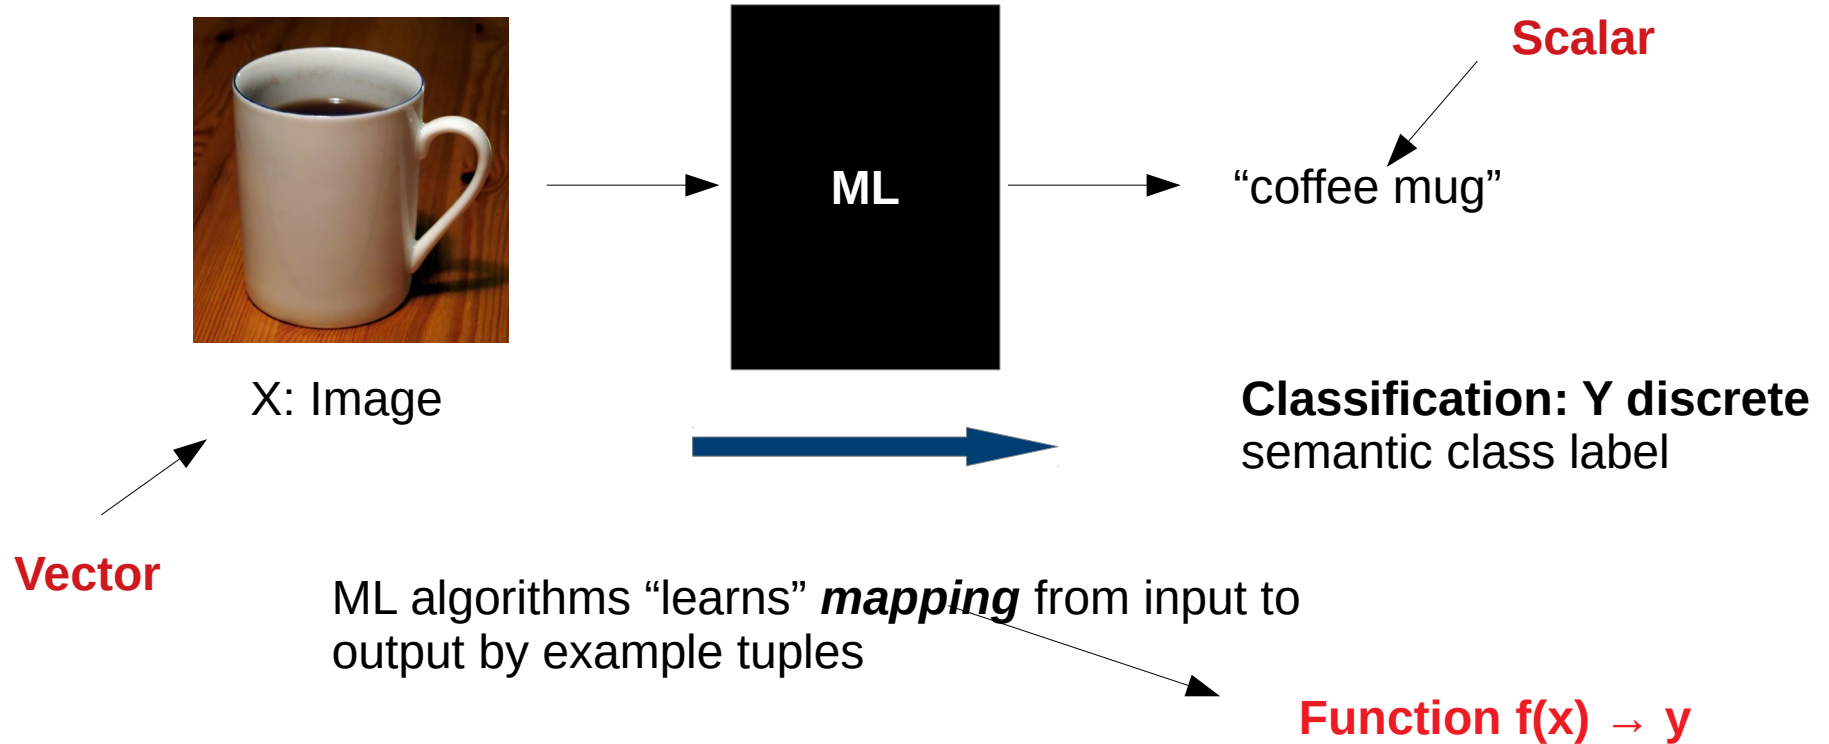

ML algorithms “learns” *mapping* from input to output by example tuples

Supervised Learning: Example: Classification

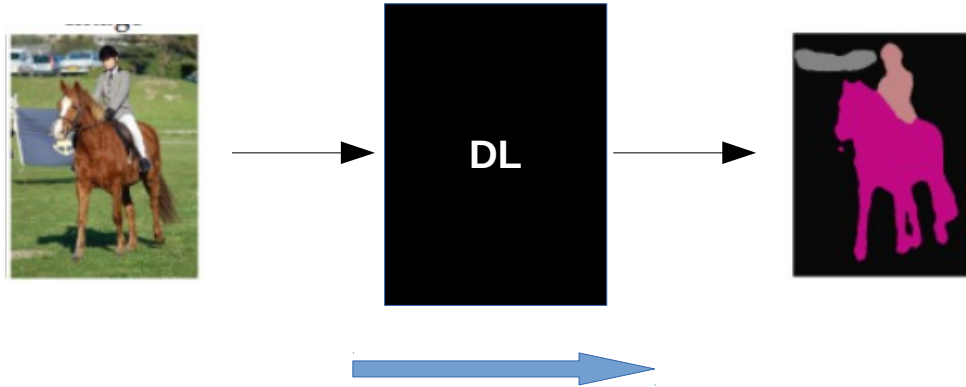

ML algorithms “learns” *mapping* from input to output by example tuples

Supervised Learning: Example: Classification

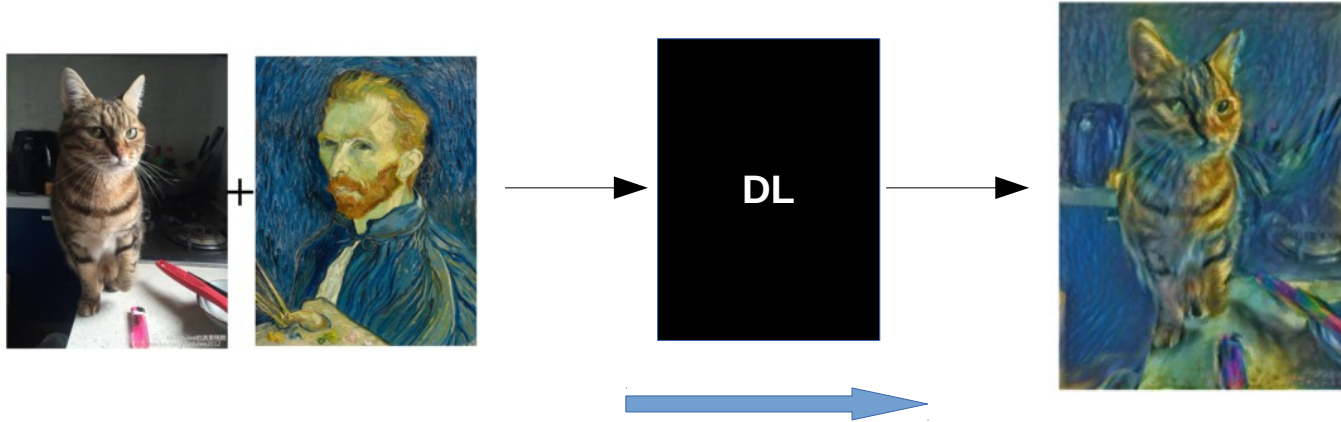

More Examples (here Deep Learning)

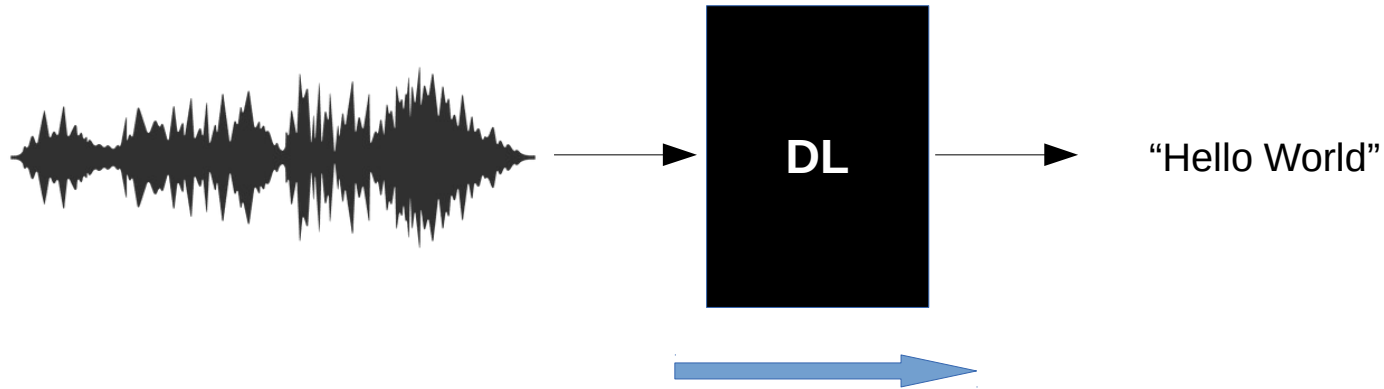

Example: semantic segmentation

More Examples (here Deep Learning)

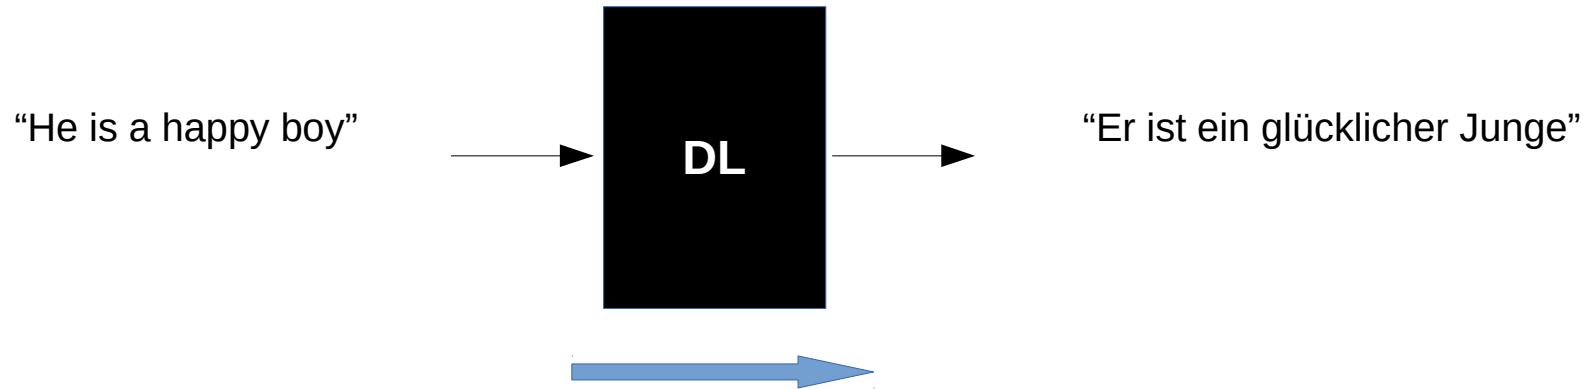

Example: content generation, e.g. style transfer learning

More Examples (here Deep Learning)

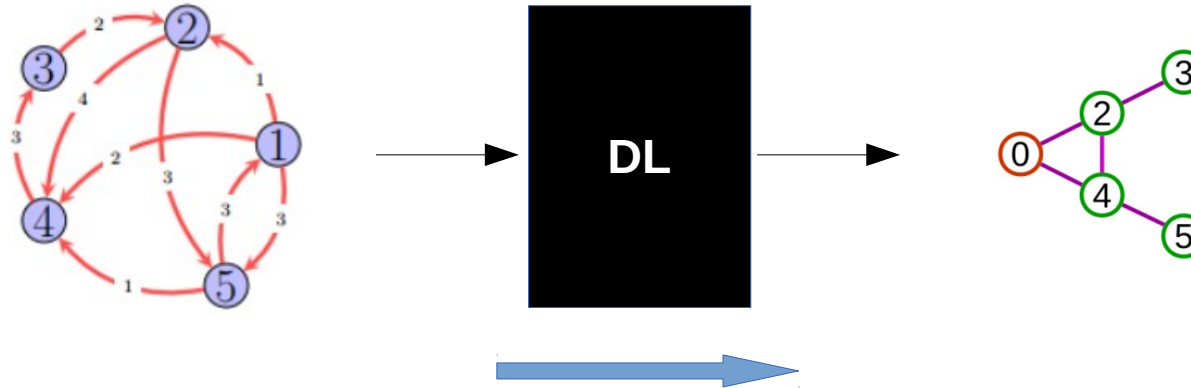

Example: Speech recognition

More Examples (here Deep Learning)

Example: Text understanding, e.g. translations

More Examples (here Deep Learning)

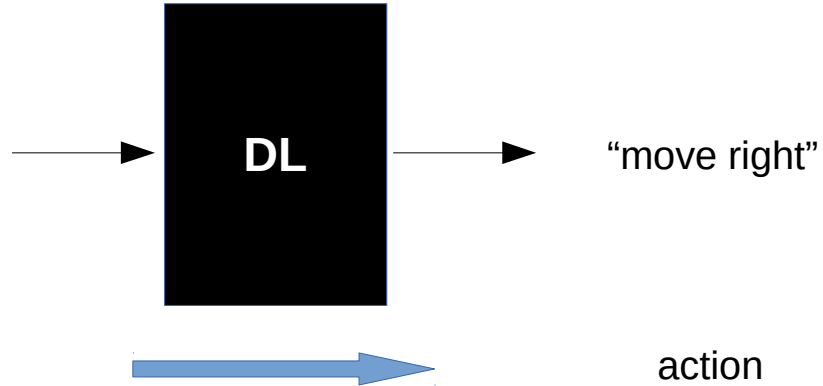

Example: Graph analysis

More Examples (here Deep Learning)

Video sequence

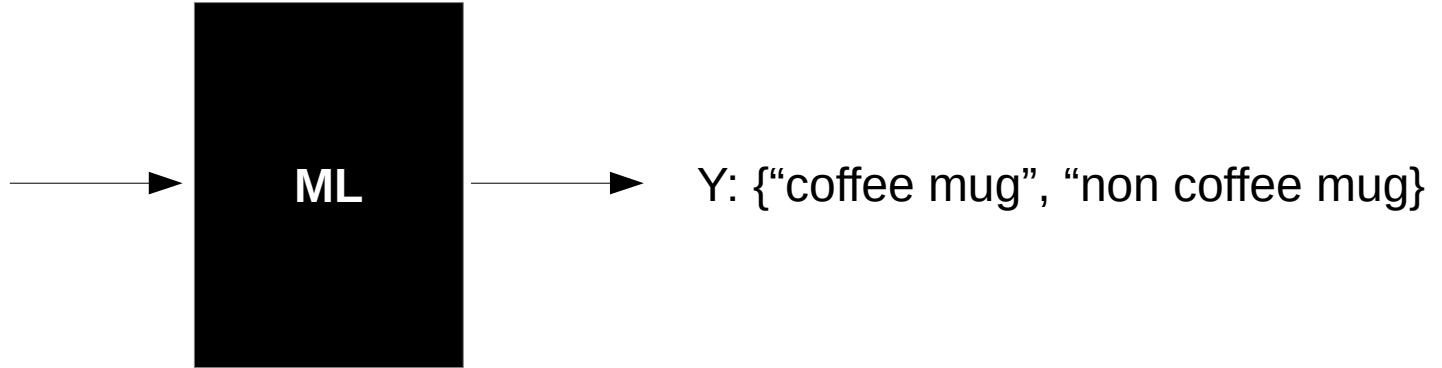

Example: game playing

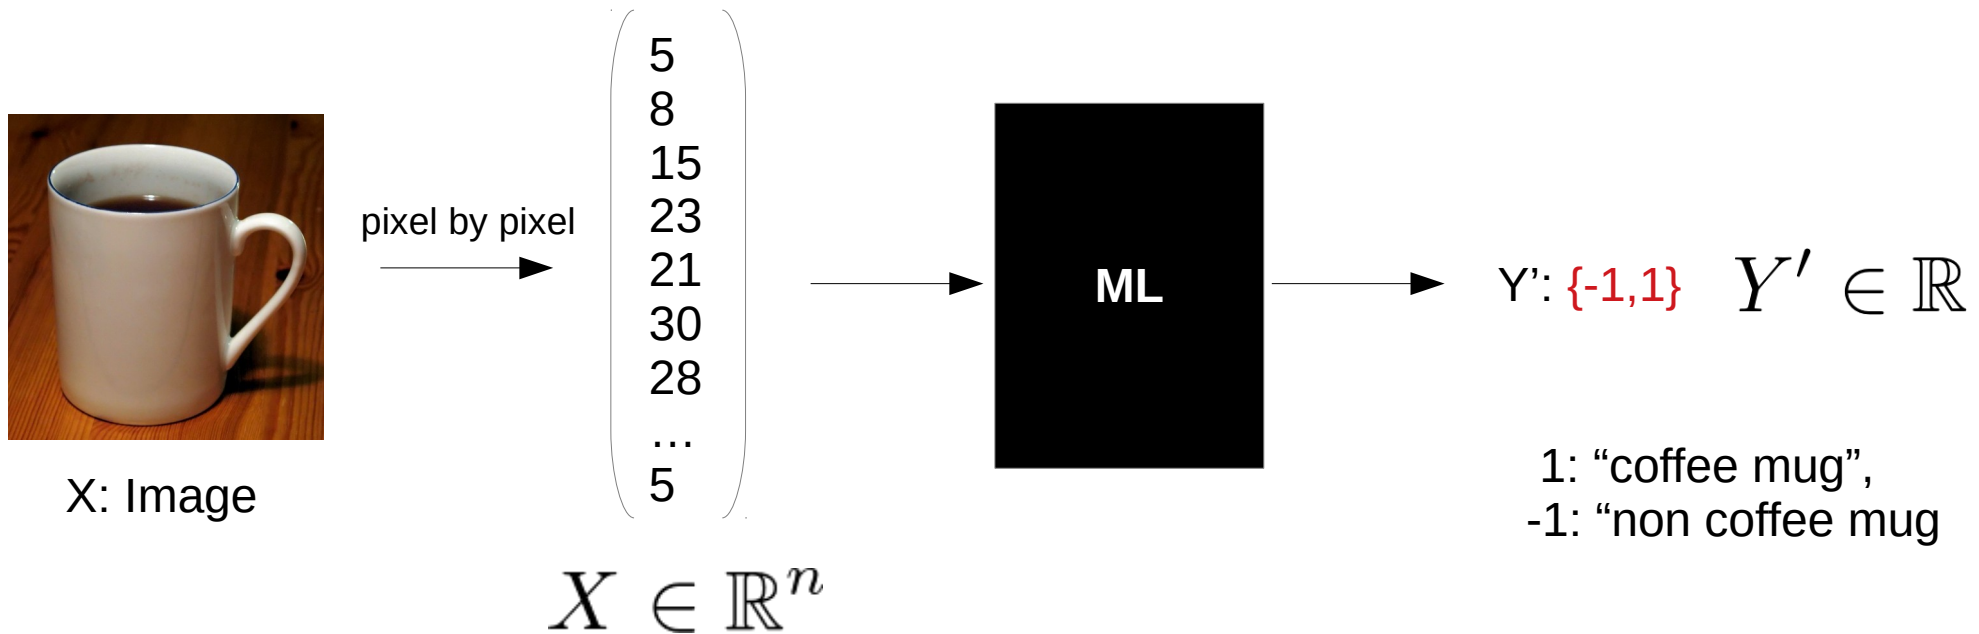

Supervised Learning: Example: Classification

X: Image

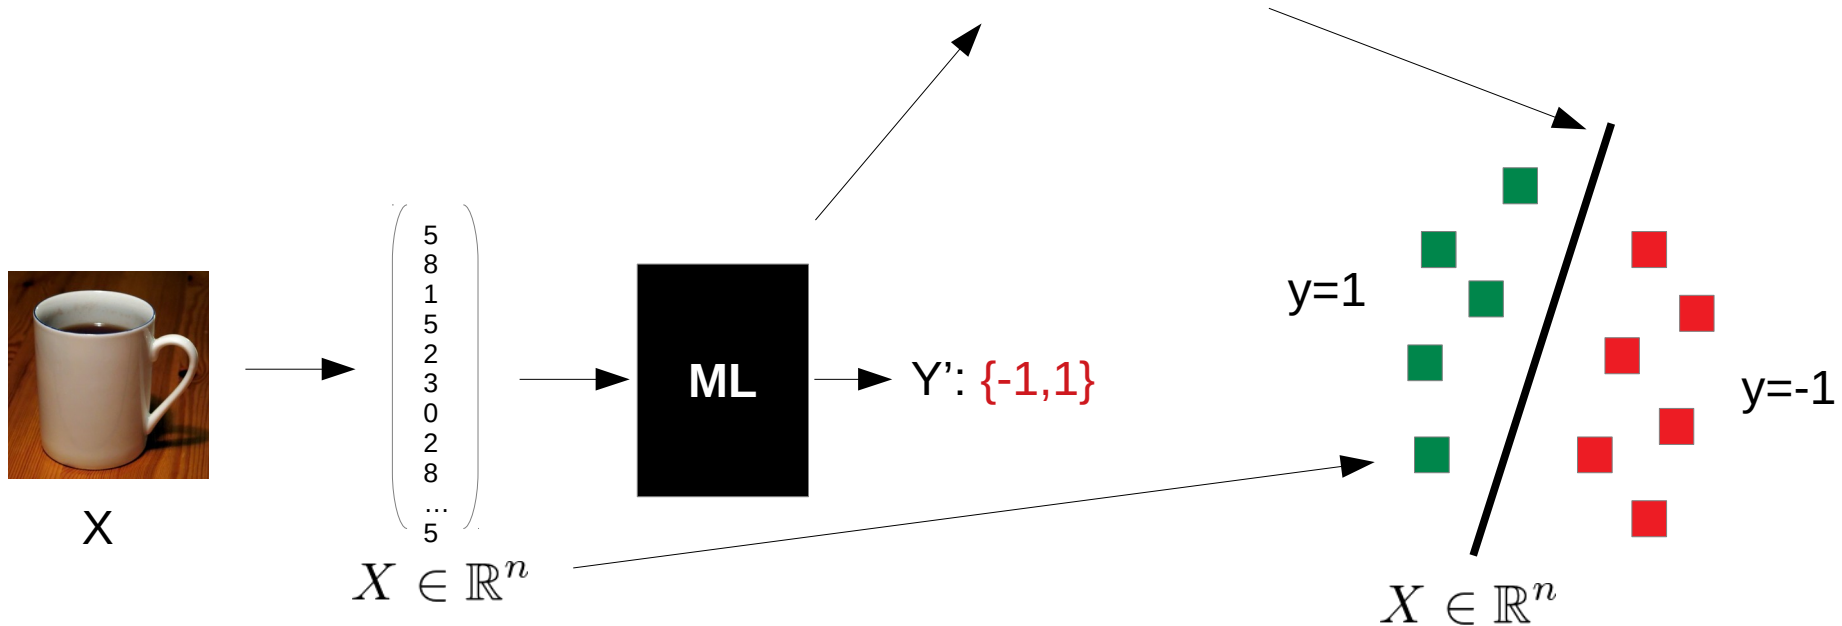

Supervised Learning: Example: Classification

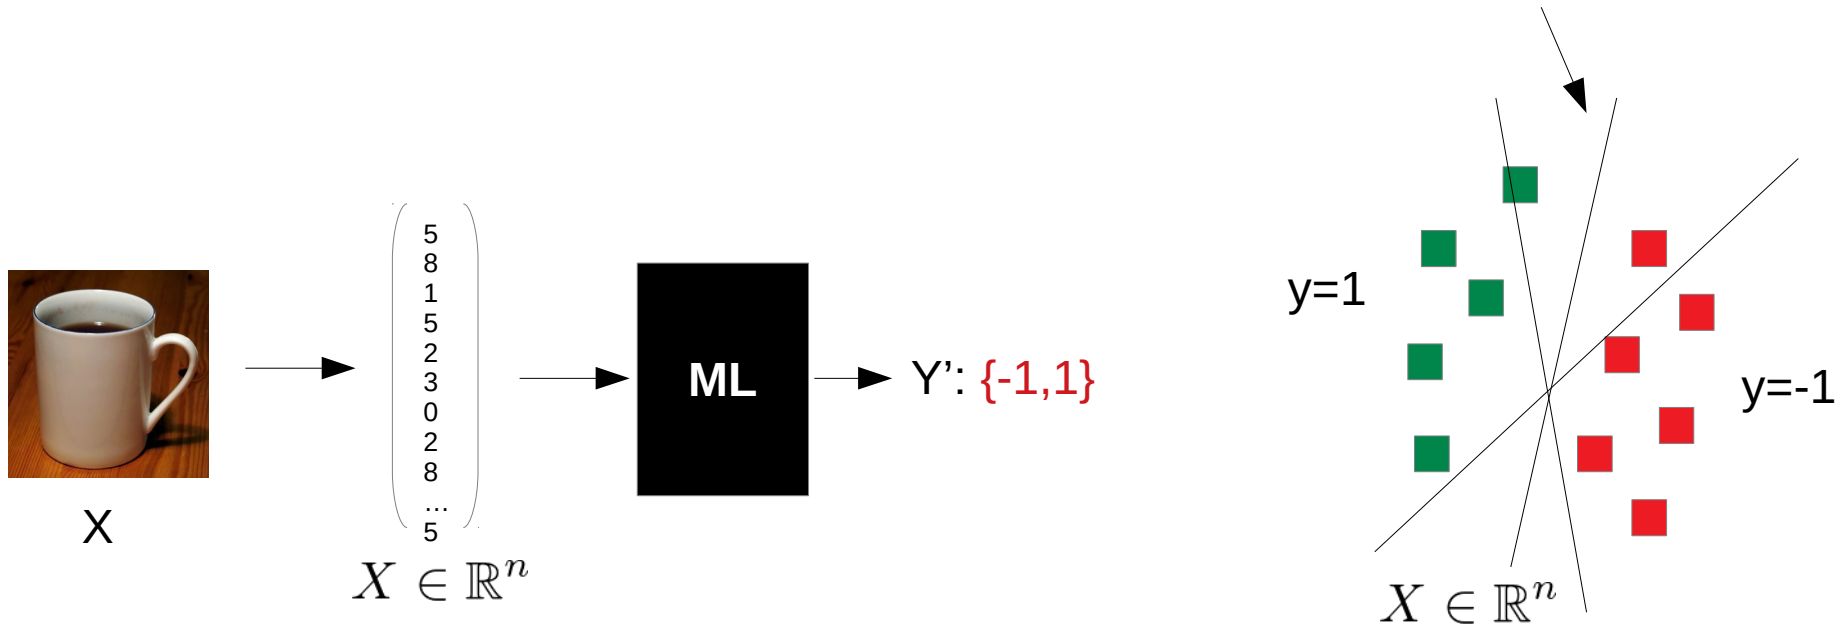

Supervised Learning: Example: Classification

ML Model: function f separating mugs from rest

Supervised Learning: Example: Classification

LEARNING: approximate „best“ f for the given data

Supervised Learning: Example: Classification

LEARNING: optimization problem:

$$\min(\|f(X, Y), Y'\|)$$

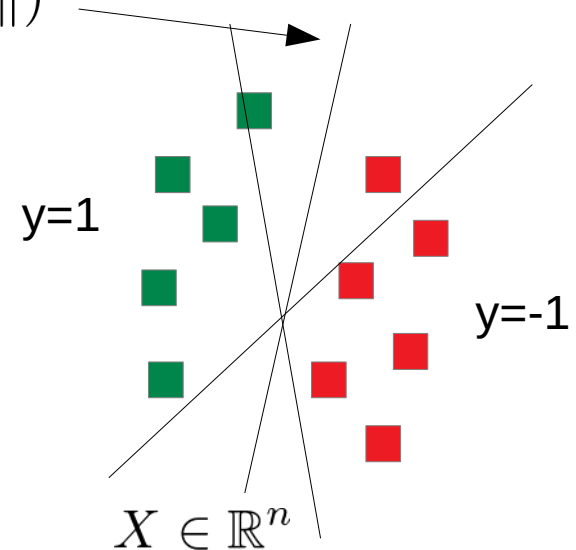

X

$$\begin{pmatrix} 5 \\ 8 \\ 1 \\ 5 \\ 5 \\ 2 \\ 3 \\ 0 \\ 2 \\ 8 \\ \dots \\ 5 \end{pmatrix}$$

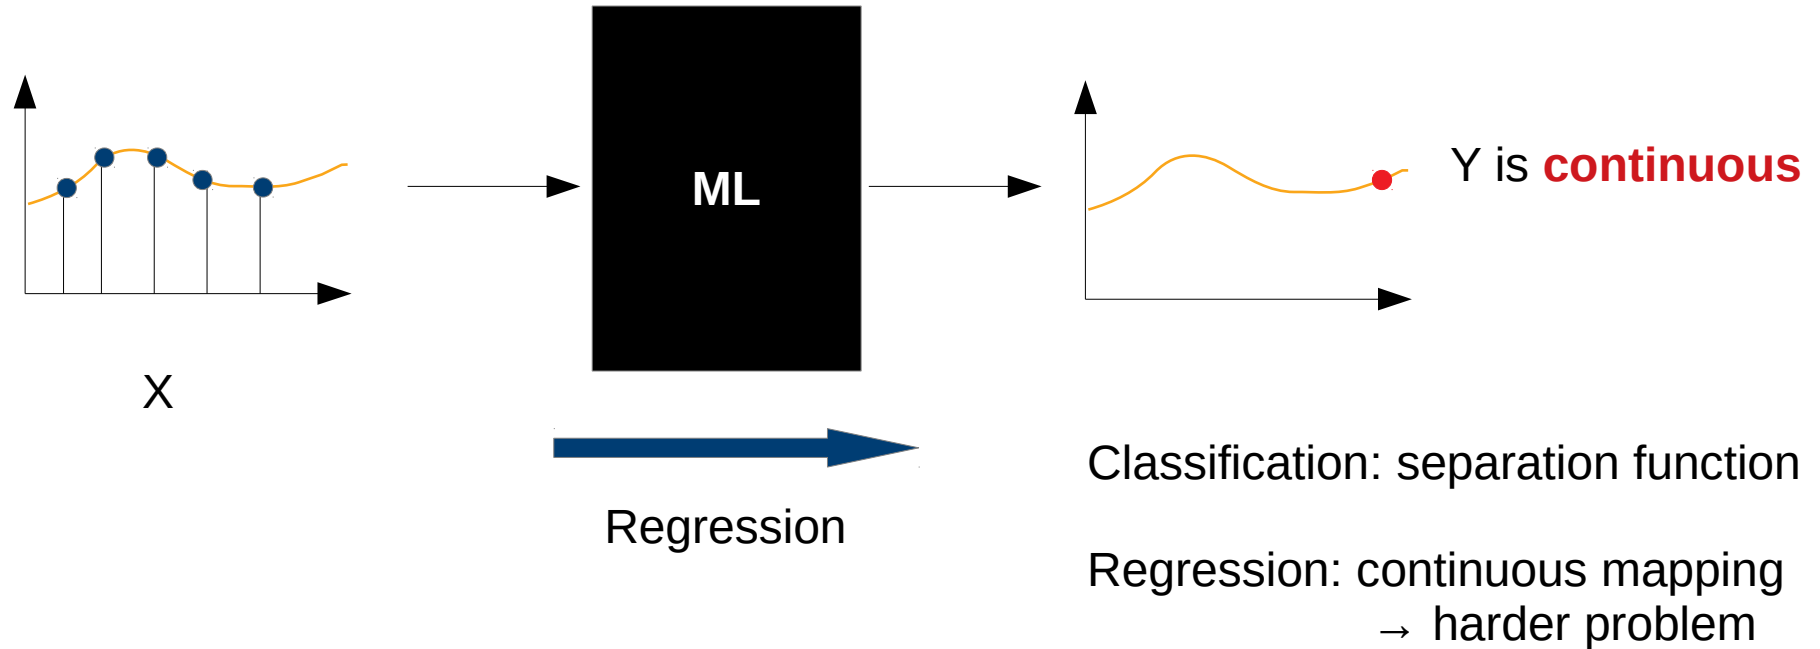

$X \in \mathbb{R}^n$

$Y': \{-1, 1\}$

Supervised Learning: Example: Regression

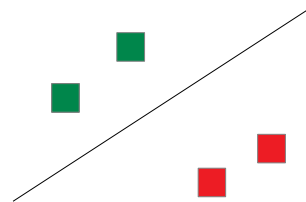

Challenges of Supervised Learning

- Not only need data – also need to have $Y \rightarrow$ human annotation
 - Getting “enough” labeled data is expensive
 - Sometimes impossible

UNDERFITTING

$$\min(\|f(X, Y), Y'\|)$$

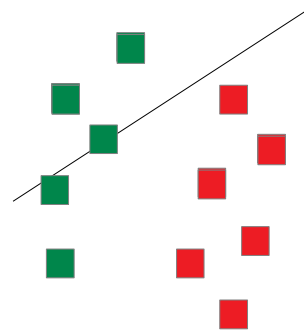

Training model
On little data

Challenges of Supervised Learning

- Not only need data – also need to have $Y \rightarrow$ human annotation
 - Getting “enough” labeled data is expensive
 - Sometimes impossible

UNDERFITTING

$$\min(\|f(X, Y), Y'\|)$$

→ bad sampling
Of the data distribution

Challenges of Supervised Learning

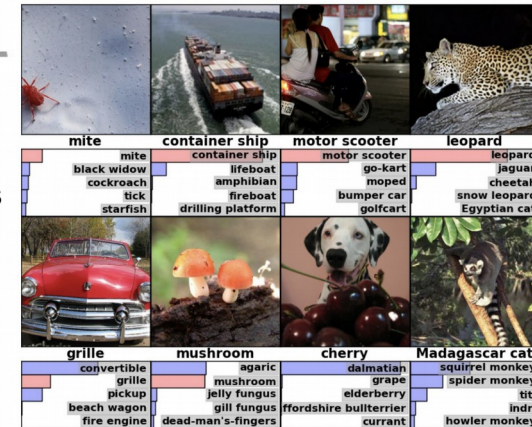

- Not only need data – also need to have $Y \rightarrow$ human annotation
 - Getting “enough” labeled data is expensive
 - Sometimes impossible

ImageNet Challenge

Example:

- 1,000 object classes (categories).
- Images:
 - 1.2 M train
 - 100k test.

IMAGENET

Challenges of Supervised Learning

- Not only need data – also need to have $Y \rightarrow$ human annotation
 - Getting “enough” labeled data is expensive
 - Sometimes impossible

Example:

Challenges of Supervised Learning

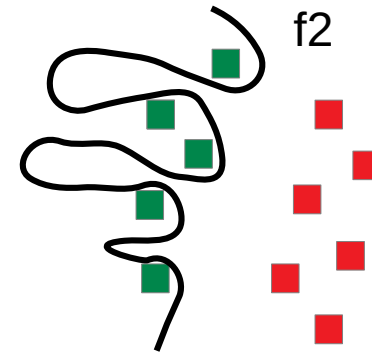

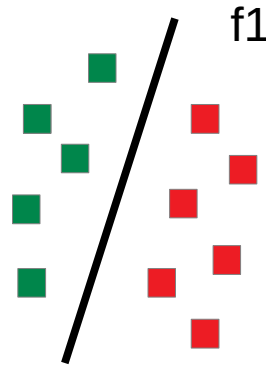

- Not only need data – also need to have $Y \rightarrow$ human annotation
 - Getting “enough” labeled data is expensive
 - Sometimes impossible
- Training data is **only a sample**: prediction must work on **all data** → **generalization**

Challenges of Supervised Learning

- Training data is **only a sample**: prediction must work on **all data** → **generalization**

Which model is better?

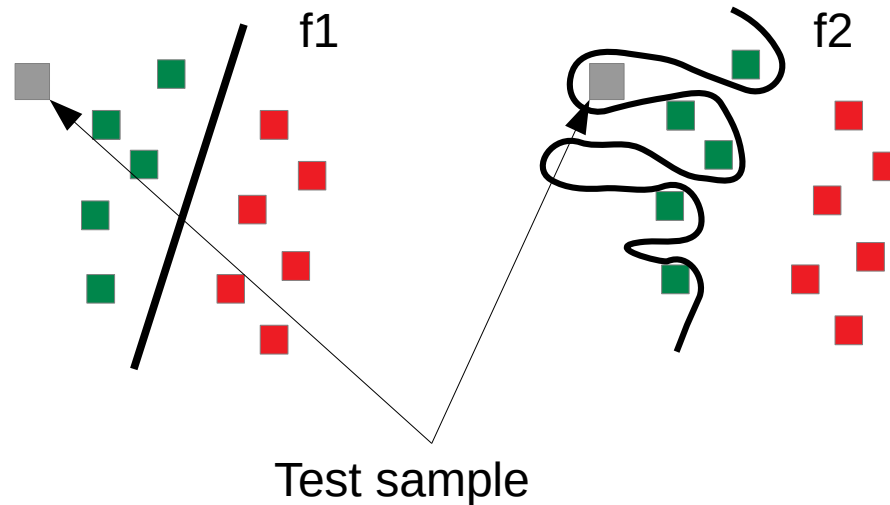

$$\min(\|f(X, Y), Y'\|)$$

Challenges of Supervised Learning

- Training data is **only a sample**: prediction must work on **all data** → **generalization**

Which model is better?
 $\min(\|f(X, Y), Y'\|)$

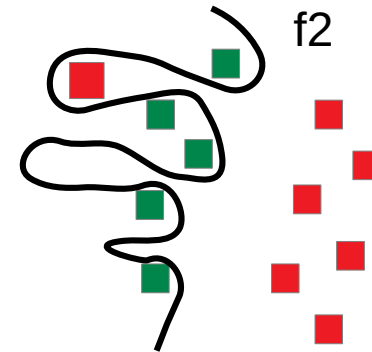

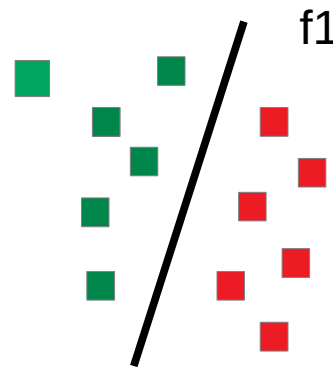

Challenges of Supervised Learning

- Training data is **only a sample**: prediction must work on **all data** → **generalization**

OVERFITTING

Model “to close” to train data

Very likely to happen in practice.
→ we need to work against this...

Data Preparation: Split into Train, Test, and Validate

A basic technique (we will learn more later) to at least detect overfitting is to split the available data into two or three subsets:

- Use unbiased **test set** for final evaluation of a model
- Use **train set** for model training
- **Validation set** (part of train set) can be used to optimize hyper parameters of the model

Caution: sets must be unbiased! (→ random sampling)
In practice it can be hard to guarantee clean train/test sets:
e.g. how to treat possible variance different data sources?
→ statistical analysis needed!

Basic Types of Machine Learning Algorithms

Supervised Learning

Unsupervised Learning

Reinforcement Learning

- NO Labeled data
- NO Direct and quantitative evaluation
- Explore structure of data

Unsupervised Learning

Data without “labels” (x_1, x_2, \dots, x_n)

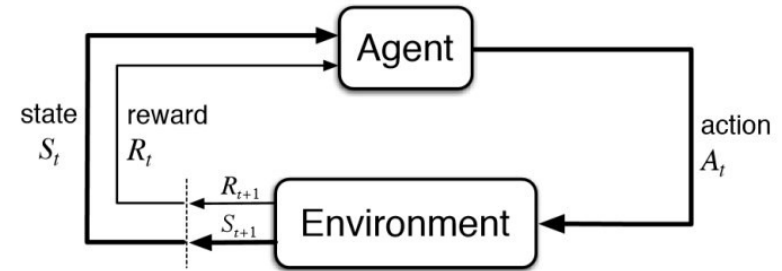

- Clustering
- Outlier Detection (e.g. Defect or Intrusion detection)

Basic Types of Machine Learning Algorithms

Supervised Learning

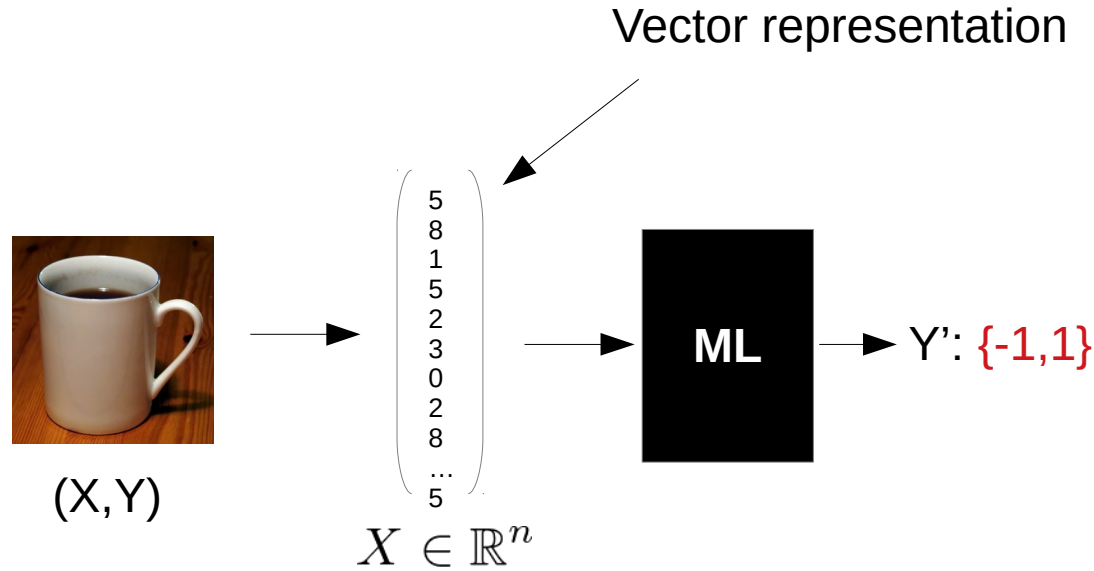

Unsupervised Learning

Reinforcement Learning

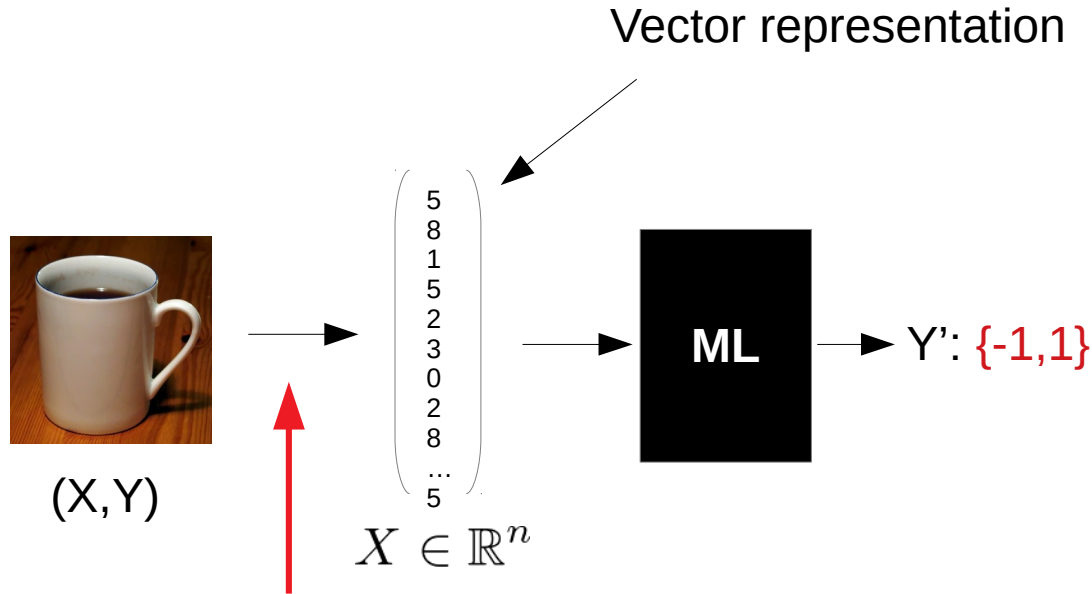

- Learning decisions in an interactive environment
- State \leftrightarrow Action learning
- Game playing and robotics
- Hardly use in Data Science

Supervised Learning: Annotated Training Data

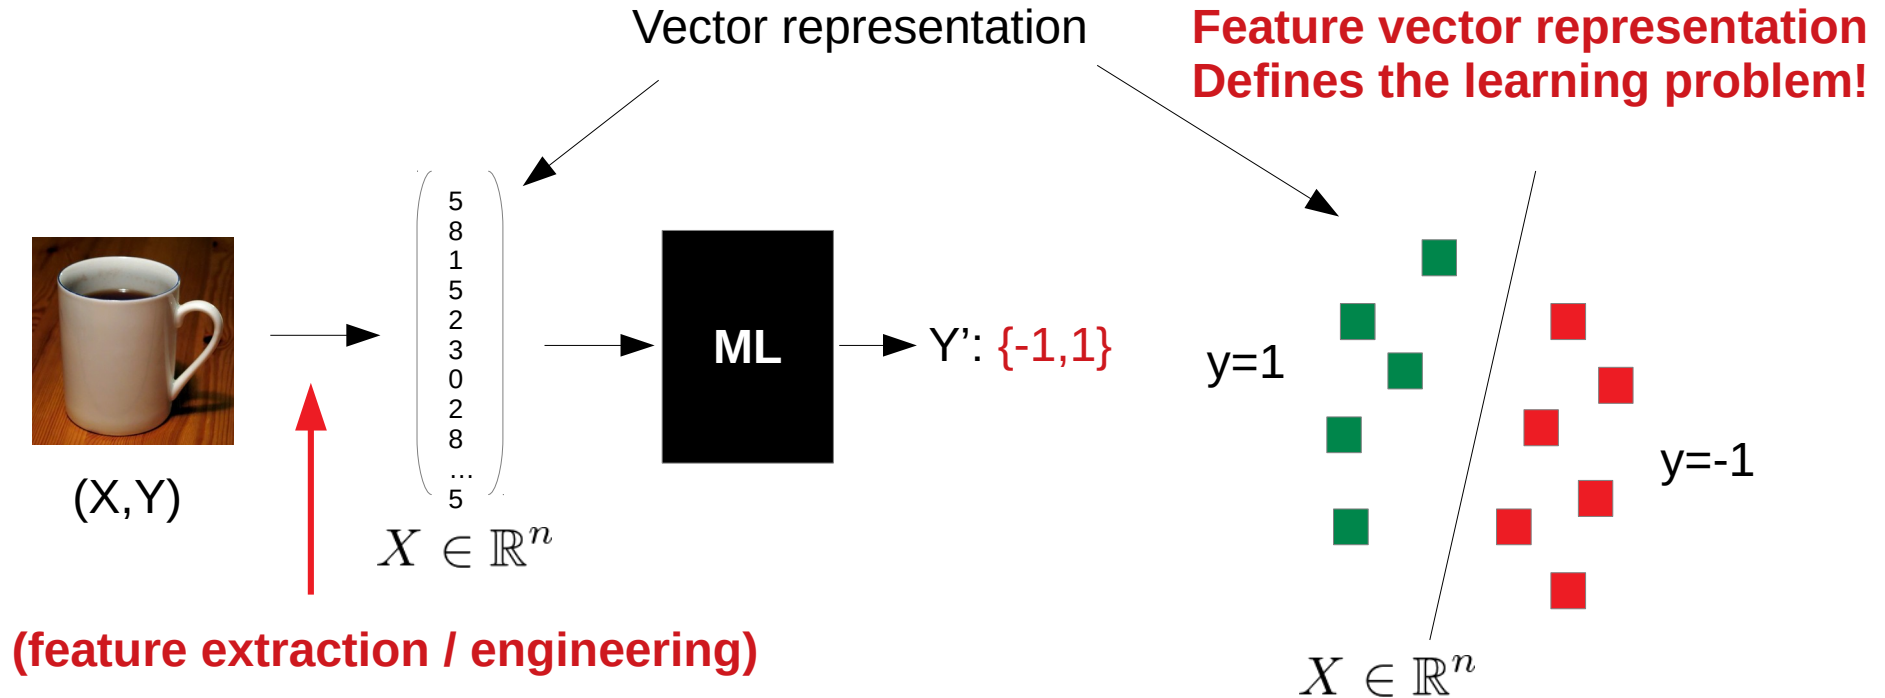

Supervised Learning: Annotated Training Data

(feature extraction / engineering)

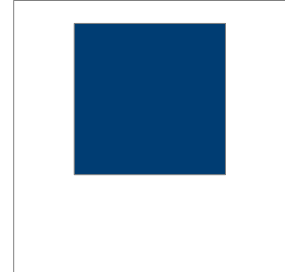

Supervised Learning: Annotated Training Data

A Simple Example

A algorithm that can classify three different shape in an image:

- How to vectorize the data samples?

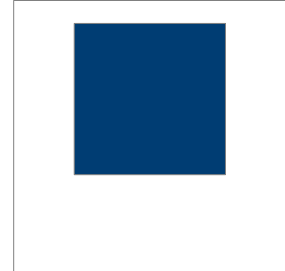

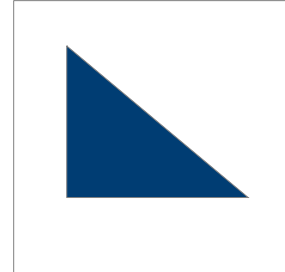

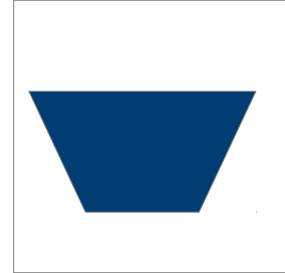

A Simple Example

A algorithm that can classify three different shape in an image:

- How to vectorize the data samples?

Naive solution: dump (raw) pixel data row by row into vector.

A Simple Example

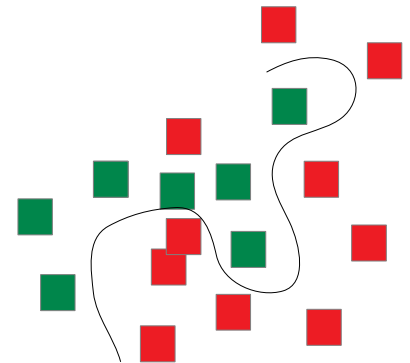

A algorithm that can classify three different shape in an image:

- How to vectorize the data samples?

Naive solution: dump (raw) pixel data row by row into vector.

- possible. BUT can become very difficult problem if we have high Variance in the data, e.g. shapes can **translate**, **scale** or even **rotate**.
- results in the need for much data (to cover the variance) and the high dimensional space. Also needs complex models (danger to overfit).

Example feature space

A Simple Example

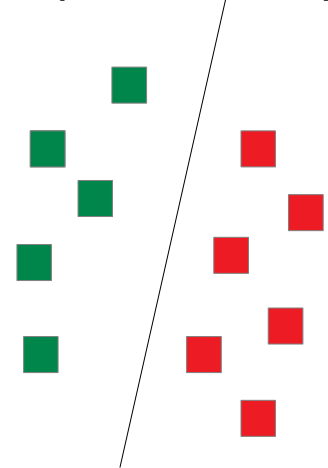

A algorithm that can classify three different shape in an image:

- How to vectorize the data samples?

Alternative: find Features $T(X)$ that **encode separable properties** of the data.

- computed by some function $T(X)$
- Compact representation of X (low dimension)
- Robust against data variance (detailed definition coming up)
- **Allows much simpler model!**

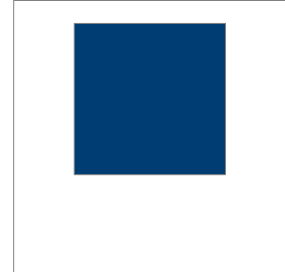

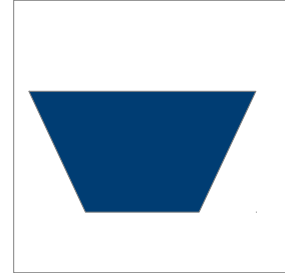

Example feature space

A Simple Example

Possible features for our problem?

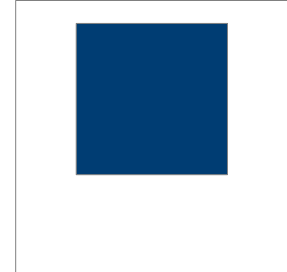

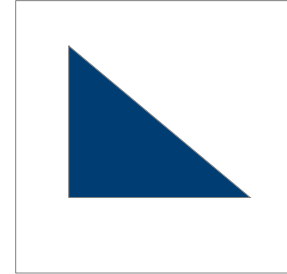

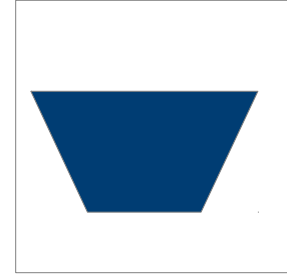

- **Number of corners**
 - requires a corner detector (standard computer vision algorithm)
 - does not change under scaling, rotation and translation (but occlusion)
 - separates triangle from other two shapes

A Simple Example

Possible features for our problem?

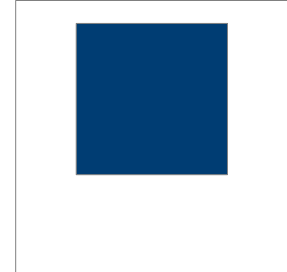

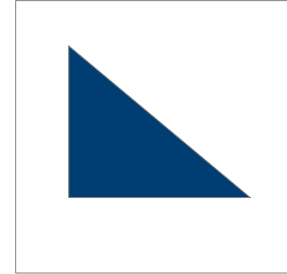

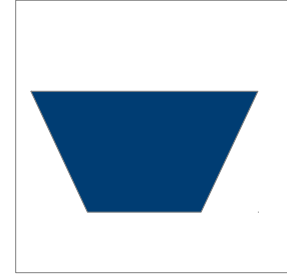

- Number of corners
- Area

A Simple Example

Possible features for our problem?

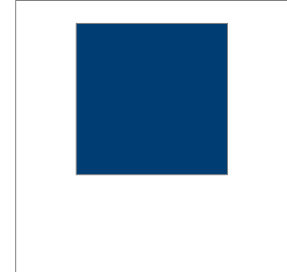

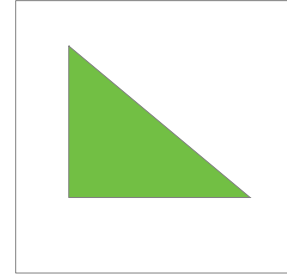

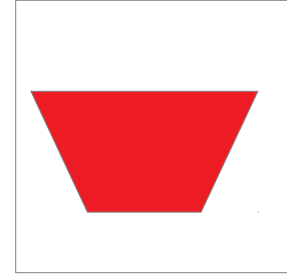

- Number of corners
- Area
- Area to circumference relation
- Max to min side length relation
- ...

A Simple Example

Possible features for our problem?

- Number of corners
- Area
- Area to circumference relation
- Max to min side length relation
- ...
- **Color !**

Invariant Theory

Example for invariant features – A classic inspection problem:

sample data

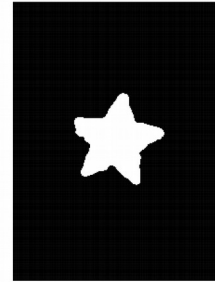

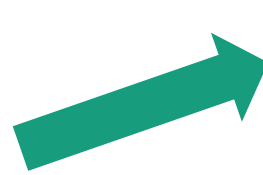

arbitrary rotations and translations

„Defect“

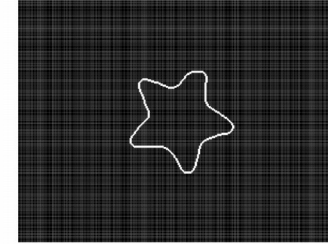

Invariant Theory

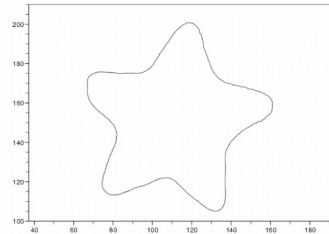

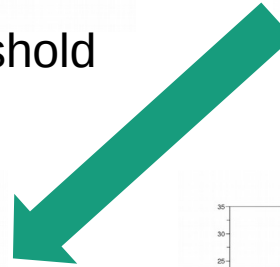

possible solution: invariant features

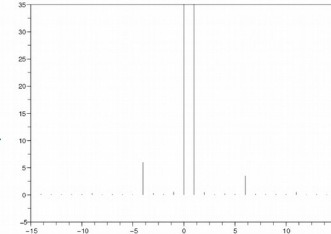

threshold

contour

polygon

Fourier spectrum

classify

Discussion:

Feature extraction vs learning algorithms

- I. if we had perfect features, learning would be trivial
- II. if we had perfect classifiers, we would not need features

Features are usually used to introduce prior knowledge about the Structure of the data and variances to the learning algorithm.

Discussion:

In practice:

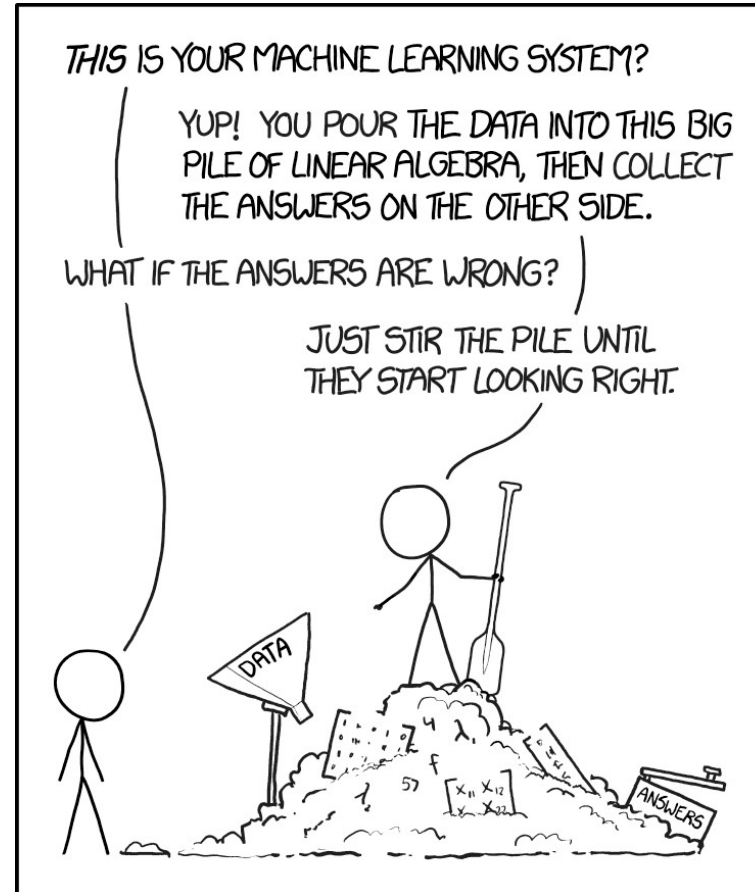

- Good features are hard to find
- Often based on complex mathematical functions
- Depend on the application (domain knowledge needed!)

Generic Approaches:

- **Invariance by differentiation:** set properties into relation / normalization
- **Invariance by integration:** compute average properties

Motivation

- Very high dimensional representations require a lot of data to fill this huge space (curse of dimensionality)
 - Danger of overfitting is higher if space is only sparsely sampled
- **We would like to “compress” our data (with steerable loss) to a lower dimensional representation**
